

Abstract

A display assembly includes a screen adapted to display images and a support structure holding the screen and being adapted to selectively rotate the screen and to mount the screen, either temporarily or permanently, to a platform such as a table. The system further includes a case mounted on the support structure with electronic circuitry receiving and processing incoming electronic signals and sending corresponding signals to the screen for display. The screen can be rotated between an upright position in which the images are visible and a rest position in which the images are not visible.
